

# Day-7:Binding Event Handlers

19 December 2022 07:49 PM

In **ReactJS**, we need to bind events so that the `this` keyword would not return an `“undefined”`.

1)Binding Event Handler in Render Method	We can bind the handler when it is called in the render method using <code>bind()</code> method.
Binding Event Handler using Arrow Function	This is pretty much the same approach as above, however, in this approach we are binding the event handler implicitly. This approach is the best if you want to pass parameters to your event.
Binding Event Handler in the Constructor	In this approach, we are going to bind the event handler inside the constructor.

## setState works in asynchronous:

After calling `setState` the `this.state` variable is not immediately changed.  
so if you want to perform an action immediately after setting state on a state variable and then return a result, a `callback` will be useful.
